Decision tree induction

Given

- Attribute-value data with nominal target variable

Induce

- A decision tree and estimate its performance on new data

Decision tree induction (ID3)

Given:
Attribute-value data with nominal target variable
Divide the data into training set (S) and test set (T)

Induce a decision tree on training set S:

1. Compute the entropy $E(S)$ of the set S
2. **IF** $E(S) = 0$
3. The current set is "clean" and therefore a leaf in our tree
4. **IF** $E(S) > 0$
5. Compute the information gain of each attribute $\text{Gain}(S, A)$
6. The attribute A with the highest information gain becomes the root
7. Divide the set S into subsets S_i according to the values of A
8. Repeat steps 1-7 on each S_i

Test the model on the test set T

Training and test set

Confusion matrix

		predicted	
		Predicted positive	Predicted negative
actual	Actual positive	TP	FN
	Actual negative	FP	TN

- Confusion matrix is a matrix showing actual and predicted classifications
- Classification measures can be calculated from it, like classification accuracy
 - = $\frac{\text{\#(correctly classified examples)}}{\text{\#(all examples)}}$
 - = $\frac{TP+TN}{TP+TN+FP+FN}$

Evaluating decision tree accuracy

Person	Age	Prescription	Astigmatic	Tear Rate	Lenses
P3	young	hypermetropes	no	normal	YES
P9	pre-presbyopic	myope	no	normal	YES
P12	pre-presbyopic	hypermetropes	no	reduced	NO
P13	pre-presbyopic	myope	yes	normal	YES
P15	pre-presbyopic	hypermetropes	yes	normal	NO
P16	pre-presbyopic	hypermetropes	yes	reduced	NO
P23	presbyopic	hypermetropes	yes	normal	NO

$Ca = \frac{3+2}{3+2+2+0} = 71\%$

	Predicted positive	Predicted negative
Actual positive	TP=3	FN=0
Actual negative	FP=2	TN=2

Discussion

- How much is the information gain for the "attribute" Person? How would it perform on the test set?
- How do we compute entropy for a target variable that has three values? Lenses = {hard=4, soft=5, none=13}
- What would be the classification accuracy of our decision tree if we pruned it at the node *Astigmatic*?
- What are the stopping criteria for building a decision tree?
- How would you compute the information gain for a numeric attribute?
